Comparison of the Bender-Gestalt and revised Developmental Test of Visual-Motor Integration.

Armstrong BB, Knopf KF.

Abstract
The Bender-Gestalt and the Developmental Test of Visual-motor Integration were administered to two groups of 40 children each, ages 7 through 10 yr. Developmental age scores (Koppitz scoring) and age equivalents (Revised Beery manual) were obtained. Children screened for learning disabilities were selected for one group and children enrolled in regular classrooms were selected for another group. The correlation of .74 between the Bender and Beery test scores was high and statistically significant for the learning-disabled group. The correlation of .36 was low though statistically significant for the regular students, which suggests the groups performed differently on the tests. A significant mean difference of 9 mo. was noted between the Bender and Beery scores.
